Customer Service Operations Notes

Operational reference for day-to-day customer contacts and handoffs between service teams

Version 3.4 | Published: March 15, 2026

Purpose

These notes provide practical handling guidance for recurring customer contacts. They are written for service agents and team leaders who need a consistent way to record cases, explain operational status and route issues to the correct team.

1. Using These Notes

The notes are intended to support day-to-day handling where several operational processes meet in the same customer conversation. They do not replace product-specific checks, carrier records, warehouse findings or payment records. When those sources contain more specific case information, use the case evidence rather than a generic script.

Agents should record what was actually verified. Phrases such as “should be fine” or “probably approved” create unnecessary follow-up when an operation is still pending.

2. Return Contacts

For standard online returns, first confirm the order, product and delivery date. The customer can normally create a return from the order detail screen. Standard return requests are handled against a 30-day window from delivery, subject to category and product conditions.

If the customer cannot see a return action, check for an existing request, split-delivery dates, product restrictions and campaign conditions before opening a manual review. Do not ask the customer to create repeated requests for the same item.

2.1 Return-shipping questions

The return code shown for a request is tied to that return flow. If a code is rejected, check the case status and whether another shipment has already been created. Order numbers, return references and carrier return codes are different identifiers and should not be used interchangeably.

Agent reminder When reading an identifier back to a customer, name the identifier as well as the value. This reduces cases where an order number is later reported as a return-shipping code.

3. Refund Contacts

A customer asking “Where is my refund?” can be at several different points in the process. Check whether the product was only delivered to the warehouse, whether the return was approved, whether a refund instruction exists and whether the payment channel has a reference.

The phrase “3-10 business days” is still commonly used in customer conversations, but it should not be treated as a guaranteed settlement commitment. The useful reference point is the actual refund instruction date and payment method.

3.1 Card payment

For card refunds, provide the refund instruction date and transaction reference where available. The bank may present a refund differently for installments, debit cards or pending authorizations.

3.2 Bank transfer

If a refund requires bank account information, verify whether the requested account holder and order owner require additional review. Incorrect account data can prevent payment even when the return itself is approved.

4. Delivery Contacts

For an order that has not arrived, determine whether the shipment is still inside the expected delivery window, delayed in carrier transit, marked delivered or returned to sender. Avoid opening a lost-shipment investigation solely because one carrier scan has not changed for a few hours.

Standard deliveries are generally expected in 2-5 business days after dispatch. Campaign periods, remote service areas and carrier incidents can change actual transit time.

5. Damaged or Incorrect Delivery

Record what the customer received and what was expected. For visible parcel damage, request images where practical and check for a carrier damage record. For an incorrect item, record product identifiers from both the order and received item.

5.1 Missing item in a multi-item order

Confirm whether the order was split into more than one shipment before treating an item as missing. If all expected shipments are delivered and an item remains missing, open a warehouse or fulfillment review.

5.2 Product appears defective

Capture the symptom in the customer's own terms and note any basic troubleshooting already completed. Do not promise automatic replacement. Some products require technical inspection before the remedy is decided.

6. Account Access

For login issues, confirm the account email or phone number without asking the customer to disclose a password. Password reset, one-time verification and account-lock behavior can differ by security flow. Use the current message shown to the customer rather than quoting a generic fixed duration from memory.

6.1 Verification codes

Never ask a customer to read a one-time security code to an agent unless the approved process explicitly requires it. If a code does not arrive, confirm contact details, wait for the standard resend interval and avoid repeated rapid requests that can trigger throttling.

7. Escalation Quality

An escalation should contain enough information for the receiving team to begin work without asking the customer to repeat the full story. Include the relevant identifiers, exact symptom or discrepancy, actions already taken and what outcome the customer is waiting for.

- Return cases: order number, return reference, delivery date, carrier tracking and current warehouse status.
- Payment cases: order number, refund instruction date, payment method and available payment reference.
- Technical cases: product model, serial number when tracked, reported symptom and troubleshooting performed.
- Account cases: account identifier, error message, affected channel and whether reset or verification attempts were made.

8. Temporary Operational Issues

When a temporary incident changes the normal customer instruction, follow the active incident note and record that the alternate instruction was used. Once the incident is closed, return to the standard flow. Temporary workarounds should not be repeated later as a permanent policy simply because they appeared in an older case.

Example A carrier integration incident may temporarily require a manual shipment reference. After the integration is restored, the normal return code should be used again.

9. Customer Commitments

Commit only to actions controlled by Nexa Retail. Agents can confirm that a review has been opened, a refund instruction was sent or a shipment was handed to a carrier. They should not guarantee the exact bank posting date, carrier delivery time or technical inspection outcome when those events are outside direct control.

10. Closing a Case

Before closing a case, verify that the customer question has been addressed and that any required follow-up belongs to a tracked operational queue. A case should not be closed only because it was transferred to another team if the transfer does not create a trackable work item.

10.1 Cases that remain open

- Warehouse mismatch under investigation.
- Carrier trace or lost-shipment investigation.
- Technical inspection awaiting result.
- Refund instruction failed or payment data requires correction.
- Security review for suspicious account activity.

11. Writing Case Notes

Case notes should separate confirmed facts from customer statements. “Carrier status shows delivered at 14:32” is different from “customer says the parcel was delivered yesterday.” Both can be recorded, but the source of the information should be clear.

Avoid copying long policy text into the case. Record the decision, the evidence used and the next action. This keeps the operational history readable and reduces contradictions between old pasted text and current process guidance.

12. Useful Status Language

- Pending review - the case is waiting for an operational or technical decision.
- In carrier transit - the parcel is moving through the carrier network and has not been received by the destination operation.
- Refund initiated - a payment instruction exists, but account posting may still be pending.
- Resolved - the requested operational action is complete and no further tracked work remains.
